- The study of the possible space-time deviations from the known laws of nature is essential for improving existing models and finding the New Physics.
- The supernovae la give an unique opportunity to make the constraints on the variation of the ⁵⁶Ni decay rate.

└─Supernovae type |a

The template

The eight standard lightcurves (UBVRIJHK) were interpolated into a common template.

▲□▶ ▲圖▶ ▲ 臣▶ ▲ 臣▶ 三臣 - のへで

Fitting function

- It appears that all the lightcurves in the given band can be fitted to the standard one by a simple contraction of the time axis and tuning the maximum intensity.
- The contraction parameter (width factor) for a lightcurve can be defined by fitting it with the template. The fitting function is:

$$I = I_0 \left[f\left(\frac{t-t_0}{w}\right) + b \right], \tag{1}$$

where f — template function, (t_0, l_0) — point of maximum, b — background.

Fitting details

- For each supernova we took the lightcurve in R band. Template curve was chosen so that the corresponding wavelength is the emitted wavelength: $\lambda = \frac{\lambda_R}{1+z}$.
- The time intervals in the supernova system of reference and on Earth differ by factor 1 + z. We see already stretched lightcurve.

Thus width factor is w = s(1 + z), where s - stretch-factor.

Constraining spacetime variations of nuclear decay rates from light curves of type Ia supernovae $\Box_{\rm Fit}$

Connection between the stretch-factor and the decay constant

- The decline of the lightcurve corresponds to the decays of ⁵⁶Ni and ⁵⁶Co - two exponents.
- Then we can get the decay constant $\lambda: I \sim \exp(-\lambda t)$
- We have calculated λ for a standard lightcurve (s = 1). It is evident that λ ~ s.

Standard lightcurve slope

The dependence of the constant λ' on the redshift

▲ロト ▲圖ト ▲画ト ▲画ト 三直 - のへで

Possible slope $\overline{\Delta\lambda'}$

◆□▶ ◆□▶ ◆三▶ ◆三▶ ●□ ● ●

Variation of the decay rate λ

$$\Delta \lambda' = 0.0168 \pm 0.0019$$
 (3)

where $\Delta\lambda' = \lambda'(z = 1.06) - \lambda'(z = 0.009819)$. Then we get:

$$rac{\Delta\lambda}{\lambda} = -0.182 \pm 0.021.$$
 (4)

So the final constraint is

$$\left|\frac{\Delta\lambda}{\lambda}\right| < 0.223 \quad (95\% \text{ CL}). \tag{5}$$

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・ ・ つ へ ()

The future work: to take into account the stellar evolution.

Constraints

The decay rate $\lambda \sim G_F^2$, Fermi coupling constant G_F is connected unambiguously to the vacuum expectation value v of the Brout-Englert-Higgs field, so that $\lambda \sim v^{-4}$. So we can get the constraints on the latter two values:

$$\left|\frac{\Delta G_F}{G_F}\right| < 0.111 \quad (95\% \text{ CL}) \tag{6}$$
$$\left|\frac{\Delta v}{v}\right| < 0.056 \quad (95\% \text{ CL}) \tag{7}$$

Variations may be constrained in a self-consistent (not dependent on the system of units) way for dimensionless constants only. The result of this work can be used for constraining a particular physical model predicting the variations of the entire set of fundamental constants.

Conclusion

- The constraints on the variations of the decay rate of ⁵⁶Ni, Fermi coupling constant and vacuum expectation of the Higgs field were calculated processing the brand new astrophysical experiment data.
- The direct result of the work constraint on the variation of the decay rate of ⁵⁶Ni — is the most precise constraint on the space-time variation of a decay rate.
- The result can be used for making constraints on the models of the New Physics.

Thank you for attention!
